12 October 2026	Automated Network Request Management in ServiceNow	Final Report

ServiceNow Project Documentation

1. INTRODUCTION

1.1 Project Overview

Automated Network Request Management in ServiceNow standardizes the way employees request new or changed network services. The solution uses a catalog-driven intake form, structured data storage, approval routing, Flow Designer automation and notifications to make request handling more consistent and traceable.

1.2 Business Objectives

- Reduce manual effort and avoidable data-entry errors.
- Accelerate request fulfilment by standardizing intake and routing.
- Enforce approval and security policies.
- Improve visibility through a centralized platform.
- Enhance end-user experience with timely status updates.
- Support auditability and operational reporting.

2. SCOPE

The initial scope includes catalog creation, form and variable design, conditional UI behaviour, custom-table record creation, approval routing, email notifications, access control and QA/UAT. Automatic provisioning through external network tools is a future enhancement unless implemented separately.

3. STAKEHOLDERS

Stakeholder	Responsibilities / expectations
End users / requesters	Submit network service requests through Service Portal. Simple form, clear required fields, status tracking, timely fulfilment.
IT administrators	Maintain ServiceNow configuration, catalog items, flows, roles and integrations. Maintainable configuration, reliable automation, controlled changes.
Network fulfilment team	Review and execute approved network changes. Complete request data, clear priority, assigned tasks and audit history.
Approvers	Managers, network security or delegated approvers review requests. Context, policy compliance, clear approve/reject action.
Security / compliance	Define and review controls for sensitive access or changes. Least privilege, evidence of approval, retention and auditability.

4. SOLUTION DESIGN

4.1 User interface

A Network Request catalog item is made available through Service Portal. Catalog variables capture requester and connection details. A Catalog UI Policy controls conditional visibility—for example, showing Existing ID when the user selects Existing connection. Mandatory fields and instructions reduce incomplete submissions.

4.2 Data architecture

A custom Network Database table stores structured request information and links to the originating Requested Item. The project plan also references a Network Task table for fulfilment work if that table is implemented. Approval records, state fields and timestamps support lifecycle tracking and reporting.

4.3 Workflow automation

Flow Designer is configured to trigger on Service Catalog submission, retrieve catalog variables, create the custom record, ask for approval, branch based on approval outcome, send email notifications and update the relevant record. The exact conditions and field mappings must match the target instance's table and variable names.

5. SECURITY AND DATA INTEGRITY

- Use table and field ACLs to restrict sensitive information.
- Require the appropriate approvals before fulfilment.
- Validate mandatory inputs and conditional fields.
- Preserve links between the catalog request and custom record.
- Review audit history and test with requester, approver and fulfiller roles.

6. TESTING AND QUALITY ASSURANCE

Testing should cover successful submission, missing mandatory data, conditional fields, record mapping, manager/security approvals, approved and rejected outcomes, email logs, role access and flow execution details. UAT and performance documents in this package provide templates; actual pass/fail results must be entered after tests are run.

7. DEPLOYMENT AND SUPPORT

- Review the deployment checklist and migrate approved configuration using the team's standard ServiceNow change process.
- Perform smoke tests after migration.
- Train requesters, approvers and fulfilment staff.
- Monitor flow execution details, email logs and request backlog.
- Assign support ownership and document rollback/escalation steps.

8. RISKS AND MITIGATIONS

Risk	Mitigation
Incomplete catalog data	Use mandatory fields, examples and validation; test negative scenarios.
Incorrect approval routing	Map request conditions to approver groups; test approve, reject and no-approver cases.
Unauthorized record access	Review table/field ACLs using requester, fulfiller and admin test roles.
Email not delivered	Inspect email logs and validate recipients, notification conditions and instance email settings.
Flow failure or timeout	Review Flow Designer execution details; add error handling and support ownership.
Deployment configuration drift	Use a checklist, update sets/app repository where appropriate, and validate after migration.

9. FUTURE ENHANCEMENTS

- Integration with network orchestration tools such as Cisco DNA Centre or Ansible, subject to security review.
- ServiceNow Integration Hub orchestration where licensed and appropriate.
- Dashboards for request volume, approval duration, fulfilment time and backlog.
- Extension to device provisioning and other IT service requests.
- Improved knowledge guidance and requester self-service.

10. CONCLUSION

The proposed ServiceNow solution brings network request intake, data capture, approval decisions, notifications and status tracking into a consistent lifecycle. With verified field mapping, tested approval paths and appropriate ACLs, it can reduce manual coordination and improve transparency. Production readiness should be confirmed through documented testing, stakeholder sign-off and post-deployment monitoring.

Appendix: project-specific implementation checklist

- Confirm catalog item name, category and portal availability.
- Confirm all variables and variable-set mappings.
- Confirm custom table names, fields and reference relationships.
- Test Flow Designer trigger and every action/condition path.
- Configure and verify approval related list and approval records.
- Test email delivery and role-based access.
- Complete UAT evidence, sign-off and deployment checklist.
