Proposed Solution Template

Automated Network Request Management in ServiceNow

Date	Project Name	Maximum Marks
12 October 2026	Automated Network Request Management in ServiceNow	2 Marks

Proposed solution

Configure an Automated Network Request Management process in ServiceNow using a Service Catalog item, catalog variables, a custom Network Database table, approval routing, Flow Designer automation and email notifications. The Service Portal provides the employee-facing entry point; internal teams use platform records and task views to process requests.

Solution components

Component	Purpose
Service Catalog item: Network Request	One standardized starting point for new and existing network connection requests.
Catalog variables and variable set	Capture requester/contact details, connection type, existing ID where relevant, justification and other approved business fields.
Catalog UI Policy	Show or require conditional fields based on selected answers; for example, show Existing ID when connection type is Existing.
Custom Network Database table	Store structured network request details, state, approval outcome and reference to the originating request.
Flow Designer	Read catalog variables, create/update records, request approvals, send emails and branch on approval outcomes.
Approval related list / records	Make approval decisions traceable and visible to authorized operators.
ACLs and roles	Protect request and configuration data according to user responsibilities.
Service Portal and notifications	Support request submission, confirmation and lifecycle updates.

Expected benefits

- Reduce repetitive manual entry and follow-up.
- Improve consistency of request data and approval decisions.
- Make request status easier to track.
- Create a clearer audit trail for approvals and fulfilment.
- Provide a maintainable foundation for future network-tool integrations.

Assumptions and boundaries

The initial scope automates intake, record creation, approval routing, notifications and lifecycle tracking. Automatic changes to routers, switches, firewalls or network infrastructure are future enhancements unless a tested integration is explicitly implemented.
